

(d) Test phase of FLS

In the test phase of FLS, the support set and query set are extracted from the source and target domain respectively (S_S and Q_T). For analysis of few-shot learning method between the novel domain instead of the novel class, we use labeled samples in the source corpus instead of the target corpus. Since we have many labeled samples, we can compare Q_T with many support sets at this time (FLS). The ensemble with the support sets yields stable comparison results and the FSL model can be reliably trained in the validation.
